Berlin, 10.11.2017

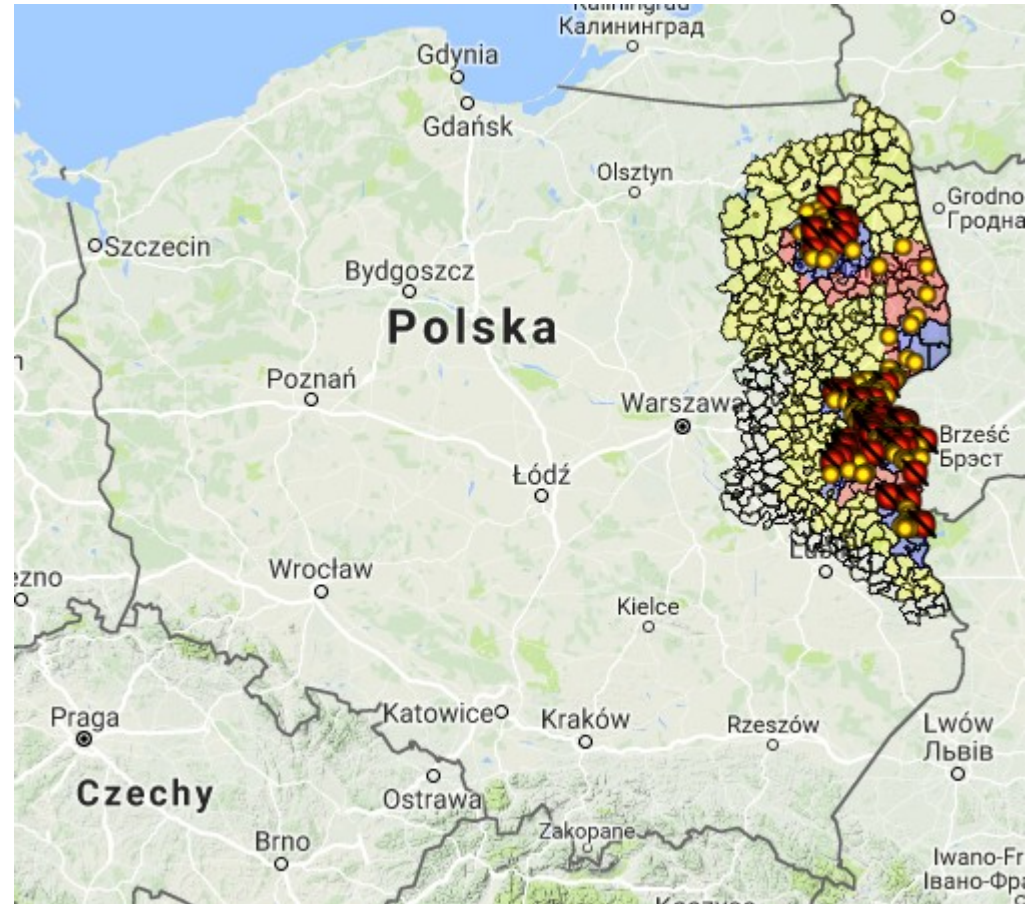

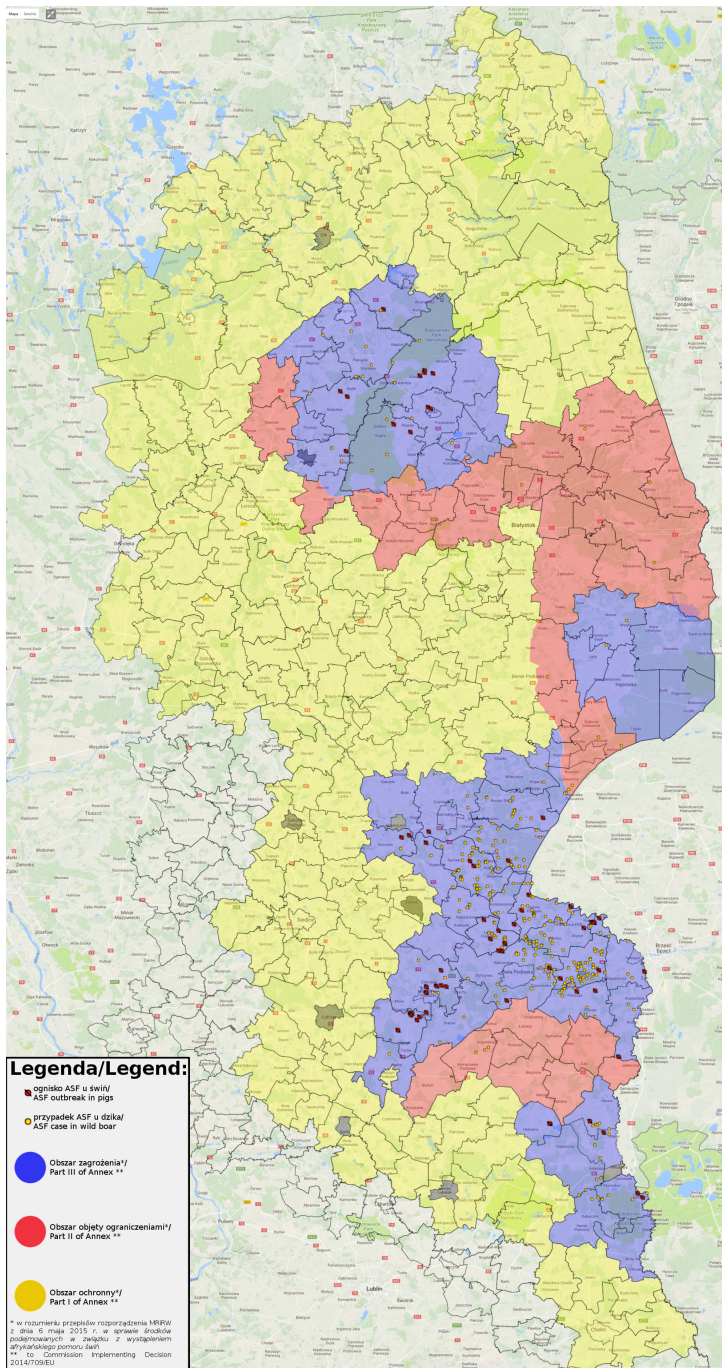

Recent rapid spread of the African Swine Fever (ASF) in the Northeast Poland during summer 2017 encourages us to prepare risk assessment for the whole country and predict future geographical transmission paths. African swine fever is viral infection which causes acute disease in domestic pigs and wild boar. Although the virus does not cause disease in humans, the impact it has on the economy, especially through trade and farming, is substantial.

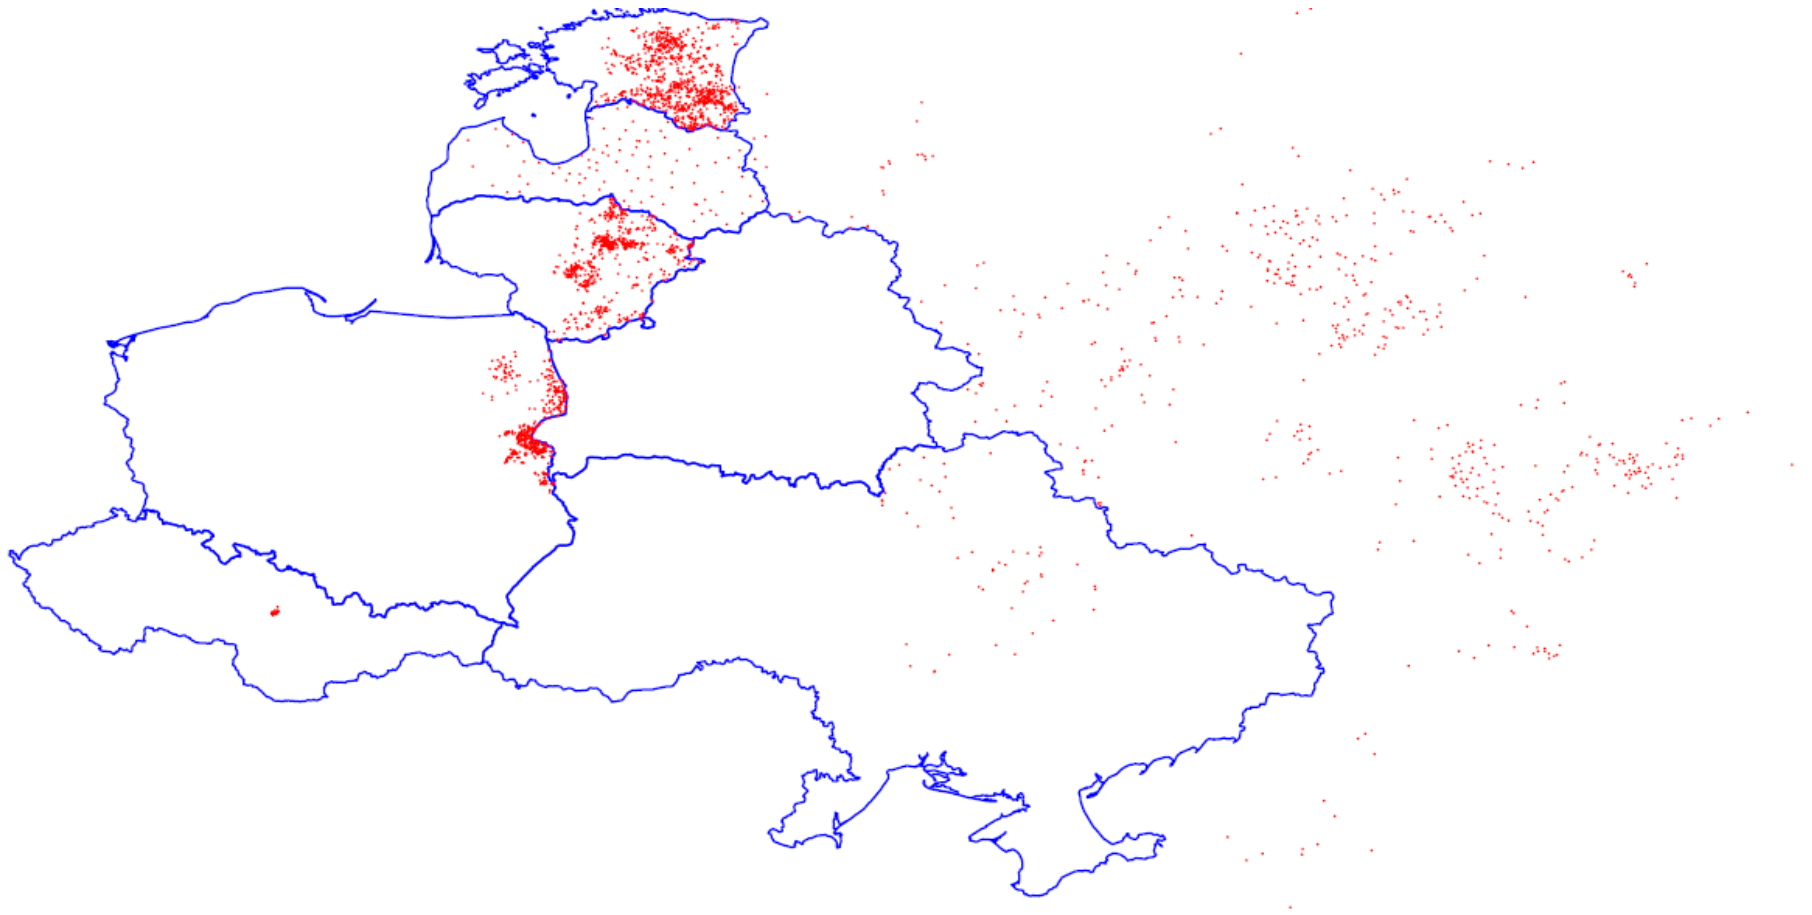

We focus on a predictive stochastic ASF model based on empirical geographical data incorporating organizational network of regions, empirical forest, swine, and wild boar density as well as theoretical organizational structure of the pork production supply chain. This model would be equipped with decision support systems as a tool for epidemiologists. In the preliminary setup, we perform outbreak investigation and simulate landscape-based propagation.

# Problem

# Problem

Data: OiE

# Problem

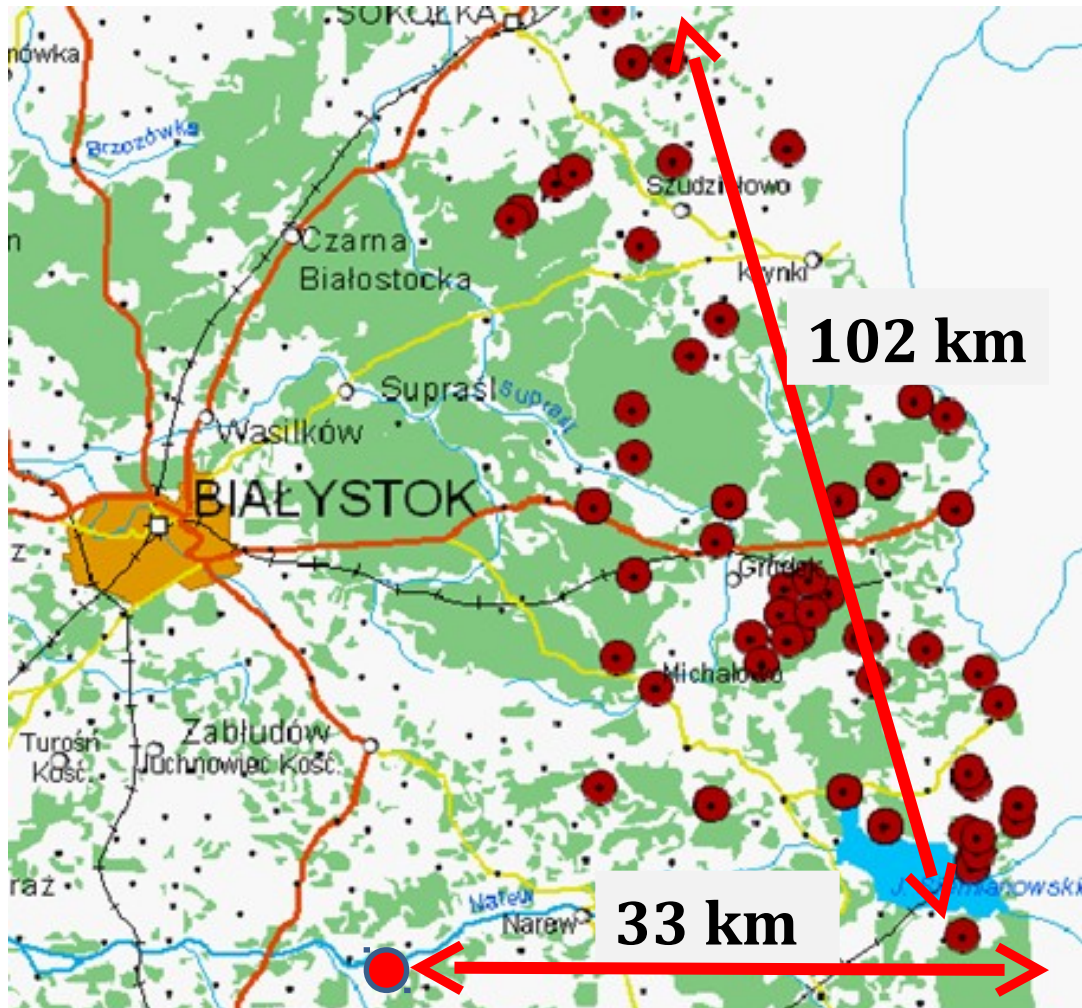

Wild boars

swines

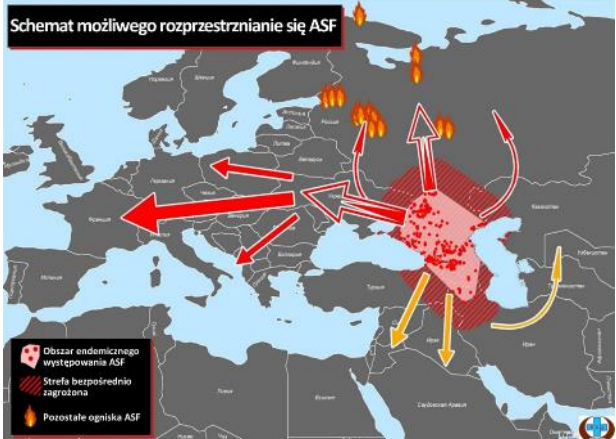

Range 2014-2016

- Single genotype with 2 branches
- Wild boars ~range 5-15km
- Human responsible for spread

# Risk

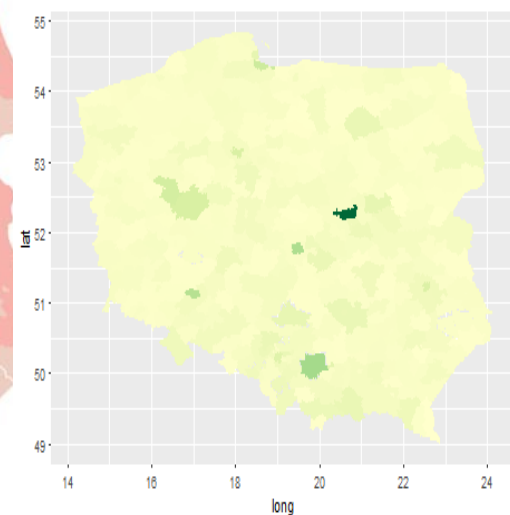

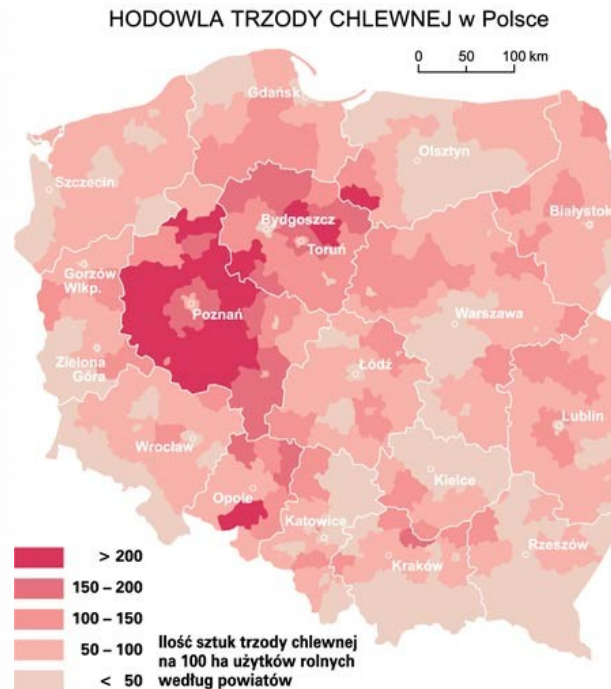

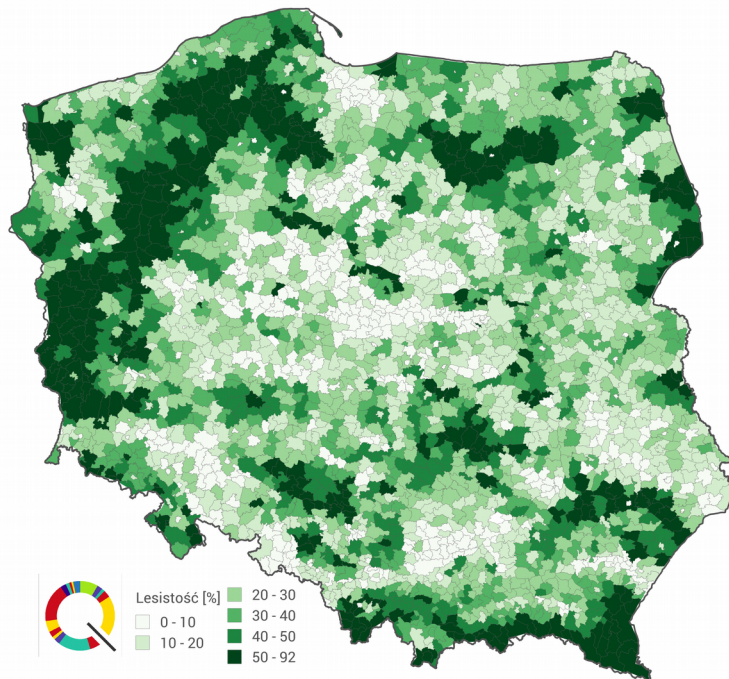

- Forest density
- Swine population
- Human population

wild boars (vectors)

swine (pathogen reservoir)

people (human mob)

- 18 affected counties (poviats) from 380 in Poland
- 3,5 years of propagation
- ~ 100 outbreaks and ~600 cases

Dependent variable: arrival time of infections

Effect	Univariate Tests of Significance for arrival_time		
	SS	F	p
dist to boarder	13405334	112.68	0.02
swine heads	41404	0.35	0.56
forest cov	386987	3.25	0.09
Error	1784447		

Dependent variable: infection in a county (0/1)

infection - Odds Ratios (powiat1)

Susceptible (S), Infectives (I), Detected (D)

Basic reproduction rate:  $R_0 = inf * durat$   
*inf* – infectivity  
*durat* – detection time/elimination time

The early detection method in zeros approximation can be done by fitting the incidence curve to the exponential function, resulting estimation of the infectivity coefficient per month ( $inf \sim 1.25$ ).

According to simplified relation in SID (Susceptible, Infectious, Detected) model  $R_0 = inf * D$ , we observe that detection and elimination time ( $D \sim 24$  days) is critical to satisfy epidemic condition ( $R_0 = 1$ ). It is enough to control epidemic with elimination time  $D$  shorter than 3 weeks (where two weeks are the time from infection to the first clinical symptoms).

Susceptible (S), Infectives (I), Detected (D)

Basic reproduction rate:  $R_0 = inf * durat$   
*inf* – infectivity  
*durat* – detection time/elimination time

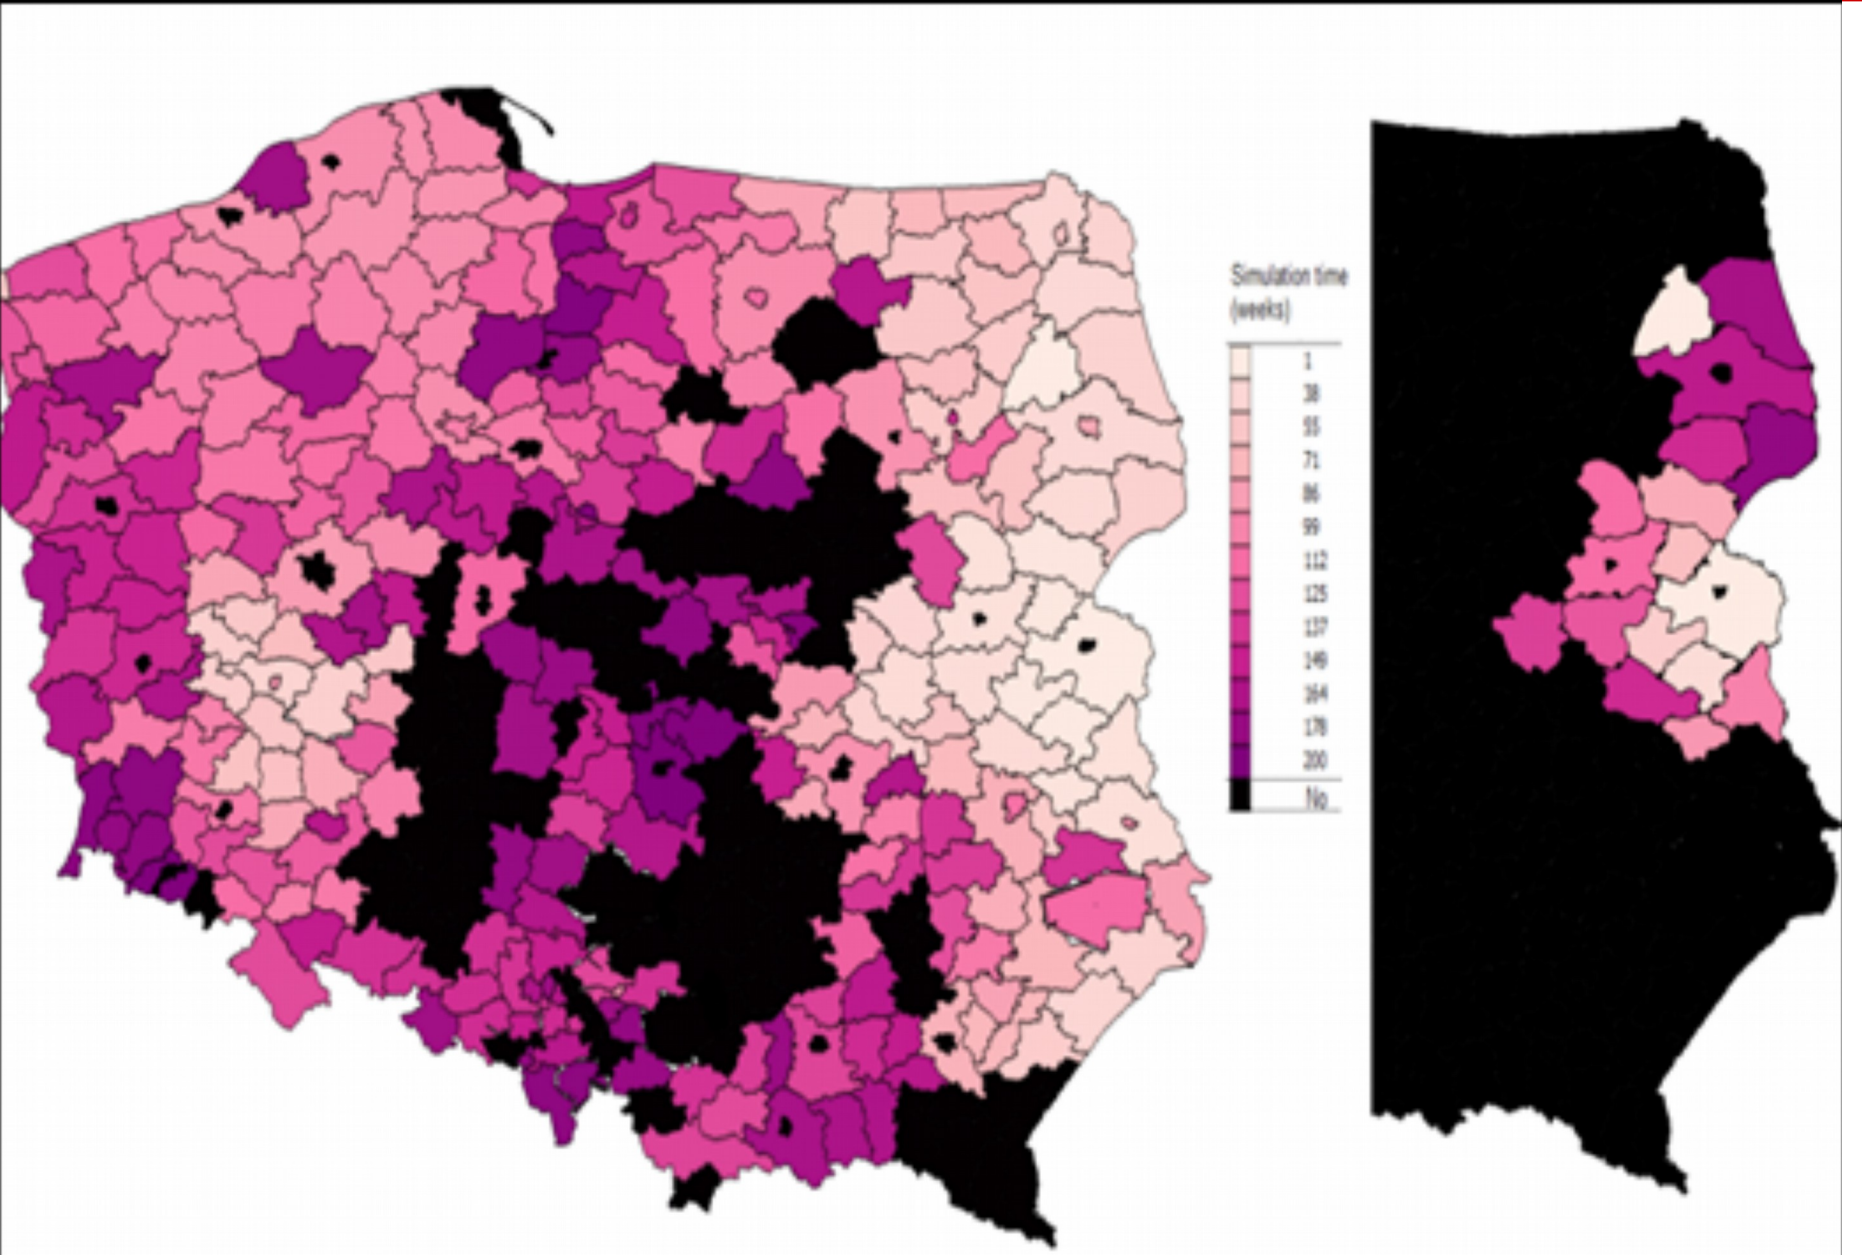

Susceptible (S), Infectives (I)

We run set of simulations for selected subspace of parameters  $a$ - swine amount significance,  $b$ - disease vectors (wild boars) significance,  $c$ - pork production chain significance.

$$p_{ij} \sim \frac{a(P_i * P_j)}{1 + d_{ij}} + \frac{b(F_i * F_j)}{1 + d_{ij}^2} + \frac{d(H_i * H_j)}{1 + d_{ij}}, \quad g_{ij} \sim p_{ij} * c$$

Where:  $a, b, c, d$  – simulation parameters;  $i, j$  – poviats;  $P$  – normalized amount of pigs;  $F$  – coverage of forests;  $p_{ij}$  -probability of infection from a neighbor;  $g_{ij}$  -probability of infection from a whole networks;  $d_{ij}$  -angular distance between centroids of poviats.

# Data – spatial - based propagation

Early epidemic growth estimation indicates that to keep the epidemiological status quo will require a very fast response from veterinary services (less than one week after detection to eliminate a single outbreak). Spatial modeling in a certain range of parameters proves the existence of a natural protective barrier within borders of the 'Congress Poland'. The spread of the disease to the 'Greater Poland' should result in the accelerated outbreak of ASF. In future analysis we will reconstruct the most likely future paths of infection and classify regions into risk groups.
